CENTER FOR ECONOMIC BEHAVIOR & INEQUALITY

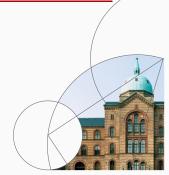

14a. HANK-SAM

Adv. Macro: Heterogenous Agent Models

Jeppe Druedahl 2023

Introduction

Introduction

Further advanced topics:

- 1. Policy analysis
- 2. Life-cycle
- 3. Endogenous idiosyncratic risk (time-varying)
- 4. Discrete choices (with taste shocks)
- 5. Bounded rationality (non-FIRE)

Introduction

Further advanced topics:

- 1. Policy analysis
- 2. Life-cycle
- 3. Endogenous idiosyncratic risk (time-varying)
- 4. Discrete choices (with taste shocks)
- 5. Bounded rationality (non-FIRE)
- Example: HANK-SAM

Broer et. al. (2023),

»Fiscal stimulus policies according to HANK-SAM«

Policies

Policies

- Policies as shocks: Choose ARMA(p,q) process and study IRFs
 (also for utility, inequality and social welfare)
 Non-linear transition: Interaction with initial state and other shocks
- 2. **Policies from targets:** Make different policies comparable by achieving the *exact* same path of outcomes
- 3. Policy rules: Parameterize and study effects on IRFs to shocks
- Optimal policy with quadratic loss function (McKay and Wolf, 2023)
 - 4.1 Easy to solve numerically with ad hoc loss function
 - 4.2 Harder to derive loss function from social welfare (Ramsey problem)
- Optimal policy: Discretion, commitment, timeless perspective (Dávila and Schaab, 2023)

Life-cycle

Households with life-cycle

- Age: $h_{it} \in \{0, 1, \dots, \#_h 1\}$
- Mortality: $\delta(h_{it}) \in [0,1], \ \delta(\#_h 1) = 1, \ \zeta(j) = \int \mathbf{1}\{h_{it} = j\}d\mathbf{D}_{ss}$
- Income profile: $\mathcal{Z}(z_{it}, h_{it+1})$
- Household problem, $\{r_t, w_t, q_t\} \rightarrow \{a_{it}, b_{it}, c_{it}, \ell_{it}\}$:

$$egin{aligned} v_0(eta_i,h_{it},z_{it},a_{it-1}) &= \max_{c_{it}} u(c_t) + eta_i (1-\delta(h_{it})) \underline{v}_{t+1} \left(eta_i,h_{it+1},z_{it+1},a_{it}
ight) \\ ext{s.t.} \ \ \ell_{it} &= z_{it} \\ a_{it} &= egin{aligned} \left(1+r_t)q_t + w_t\ell_{it} - c_{it} + \Pi_t & \text{if } h_{it} = 0 \\ \left(1+r_t)a_{it-1} + w_t\ell_{it} - c_{it} + \Pi_t & \text{else} \end{aligned} \\ b_{it} &= \delta(h_{it})a_{it} \\ h_{it+1} &= egin{aligned} 0 & \text{with prob. } \delta(h_{it}) \\ h_{it} + 1 & \text{else} \end{aligned} \\ z_{it+1} \sim \mathcal{Z}(z_{it},h_{it+1}), \ \mathbb{E}\left[z_{it}\right] = 1 \\ a_{it} &> 0 \end{aligned}$$

Equation system

$$\begin{split} \boldsymbol{H}(\boldsymbol{K},\boldsymbol{q},\boldsymbol{\Gamma},\underline{\boldsymbol{D}}_0) &= \begin{bmatrix} A_t - A_t^{hh} \\ \zeta(0)q_t - B_{t-1}^{hh} \\ \forall t \in \{0,1,\dots,T-1\} \end{bmatrix} = \boldsymbol{0} \end{split}$$
 where $K_{-1} = \int a_{t-1}d\underline{\boldsymbol{D}}_0$ and
$$L_t = 1 \\ A_t = K_t \\ r_t^K &= \alpha \Gamma_t (K_{t-1}/L_t)^{\alpha-1} \\ w_t &= (1-\alpha)\Gamma_t (K_{t-1}/L_t)^{\alpha} \\ \boldsymbol{D}_t &= \Pi_z'\underline{\boldsymbol{D}}_t \\ \underline{\boldsymbol{D}}_{t+1} &= \Lambda_t'\boldsymbol{D}_t \\ A_t^{hh} &= a_t^{*\prime}'\boldsymbol{D}_t \\ \forall t \in \{0,1,\dots,T-1\} \end{split}$$

Endogenous idiosyncratic risk

Consumption problem

Recursive household problem:

$$\begin{aligned} v_t(u_{it}, a_{it-1}) &= \max_{c_{it}} u(c_{it}) + \beta \underline{v}_t \left(u_{it}, a_{it} \right) \\ \text{s.t.} \\ a_{it} &= (1 + r_t) a_{it-1} + y_{it} - c_{it} \\ y_{it} &= (1 - \tau_t) w_t \cdot \begin{cases} 1 & \text{if } u_{it} = 0 \\ \phi \in (0, 1) & \text{if } u_{it} = 1 \end{cases} \\ a_{it} &\geq 0 \end{aligned}$$

- Working if $u_{it} = 0$, unemployed if $u_{it} = 1$
- Solution method: Standard EGM

External endogenous risk

Expectation step:

$$\underline{v}_t(u_{it-1}, a_{it-1}) = \mathbb{E}\left[v_t(u_{it}, a_{it-1}) \mid u_{it-1}, a_{it-1}, \delta_t, \lambda_t^u\right]$$
 s.t.
$$\pi_t(u_{it} \mid u_{it-1}) = \begin{cases} \delta_t & \text{if } u_{it} = 1 \text{ and } u_{it-1} = 0 \\ 1 - \delta_t & \text{if } u_{it} = 0 \text{ and } u_{it-1} = 0 \\ \lambda_t^u & \text{if } u_{it} = 0 \text{ and } u_{it-1} = 1 \\ 1 - \lambda_t^u & \text{if } u_{it} = 1 \text{ and } u_{it-1} = 1 \end{cases}$$

- Stochastic transition matrix: $\Pi_{t,z} = \Pi_z(\delta_t, \lambda_t^u)$
- Envelope condition: Nothing changed
- Transition steps:

$$oldsymbol{D}_t = \Pi'_{t,z} \underline{oldsymbol{D}}_t \ \underline{oldsymbol{D}}_{t+1} = \Lambda'_t oldsymbol{D}_t$$

Internal endogenous risk

Expectation step:

$$\underline{v}_t(u_{it-1}, a_{it-1} \mid s_{it}) = \mathbb{E}\left[v_t(u_{it}, a_{it-1}) \mid u_{it-1}, a_{it-1}, s_{it}, \delta_t, \lambda_t^{u,s}\right]$$
s.t.
$$\pi_t(u_{it} \mid u_{it-1}, s_{it}) = \begin{cases} \delta_t & \text{if } u_{it} = 1 \text{ and } u_{it-1} = 0\\ 1 - \delta_t & \text{if } u_{it} = 0 \text{ and } u_{it-1} = 0\\ \lambda_t^{u,s} s_{it} & \text{if } u_{it} = 0 \text{ and } u_{it-1} = 1\\ 1 - \lambda_t^{u,s} s_{it} & \text{if } u_{it} = 1 \text{ and } u_{it-1} = 1 \end{cases}$$

Search decision:

- 1. Discrete search choice: $s_{it} \in \{0, 1\}$
- 2. Search cost: λ if $s_{it} = 1$
- 3. Taste shocks: ε (s_{it}) \sim Extreme value (Iskhakov et. al., 2017)
- See also: Bardóczy (2021)

Discrete search decision

Standard logit formula:

$$\begin{split} \underline{v}_t(u_{it-1}, a_{it-1}) &= \max_{s_{it} \in \{0, 1\}} \left\{ \underline{v}_t(u_{it-1}, a_{it-1} \mid s_{it}) - \lambda \mathbf{1}_{s_{it}=1} + \sigma_{\varepsilon} \varepsilon \left(s_{it}\right) \right\} \\ &= \sigma_{\varepsilon} \log \left(\exp \frac{\underline{v}_t(u_{it-1}, a_{it-1} \mid 0)}{\sigma_{\varepsilon}} + \exp \frac{\underline{v}_t(u_{it-1}, a_{it-1} \mid 1)}{\sigma_{\varepsilon}} \right) \end{split}$$

Transition matrix:

$$\Pi_{t,z} = \Pi_z \left(\left\{ r_\tau, w_\tau, \tau_\tau, \delta_\tau, \lambda_\tau^{u,s} \right\}_{\tau \ge t} \right)$$

Envelope condition

Choice probabilities:

$$P_t(s \mid u_{it-1}, a_{it-1}) = \frac{\exp \frac{\underline{v}_t(u_{it-1}, a_{it-1} \mid s)}{\sigma_{\xi}}}{\sum_{s' \in \{0,1\}} \exp \frac{\underline{v}_t(u_{it-1}, a_{it-1} \mid s')}{\sigma_{\xi}}}$$

Envelope condition:

$$\underline{v}_{a,t}(u_{t-1}, a_{t-1}) = \sum_{s \in \{0,1\}} P_t(s \mid u_{it-1}, a_{it-1}) \pi_t(u_{it} \mid u_{it-1}, s) v_{a,t}(u_{it}, a_{it-1})$$

$$= \sum_{s \in \{0,1\}} P_t(s \mid u_{it-1}, a_{it-1}) \pi_t(u_{it} \mid u_{it-1}, s) c_t^*(u_{it}, a_{it-1})^{-\sigma}$$

- Break of monotonicity ⇒ FOC still necessary, but not sufficient
 - 1. **Normally:** Savings $\uparrow \Rightarrow$ future consumption $\uparrow \Rightarrow$ marginal utility \downarrow
 - Now also: Future search jump ↓ ⇒ future income ↓
 ⇒ future consumption ↓ ⇒ marginal utility ↑

Upper envelope for given z^{i_z}

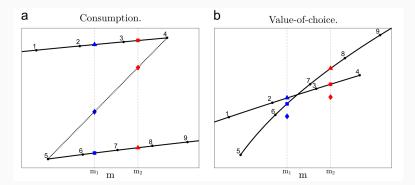

1. Generate candidate points: $\forall i_a \in \{0, 1, \dots, \#_a - 1\}$

$$w^{i_a} = \beta \underline{v}_{t+1}(z^{i_z}, a^{i_a})$$
 $c^{i_a} = u'^{-1} (\beta \underline{v}_{a,t+1}(z^{i_z}, a^{i_a}))$
 $m^{i_a} = a^{i_a} + c^{i_a}$
 $v^{i_a} = u(c^{i_a}) + w^{i_a}$

2. Apply upper-envelope: $\forall i_{a-} \in \{0, 1, \dots, \#_a - 1\}$

$$\begin{split} c^*(a^{i_{3-}}) &= \max_{j \in \{0,1,\dots\#_{s}-2\}} u\left(c^{i_{3-}}\right) + w^{i_{3-}} \text{ s.t.} \\ m^{i_{3-}} &= (1+r_t)a^{i_{3-}} + w_t z^{i_z} \in \left[m^j, m^{j+1}\right] \\ c^{i_{3-}} &= \min\left\{\text{interp }\left\{m^{i_{3}}\right\} \to \left\{c^{i_{3}}\right\} \text{ at } m^{i_{3-}}, m^{i_{3-}}\right\} \\ a^{i_{3-}} &= m^{i_{3-}} - c^{i_{3-}} \\ w^{i_{3-}} &= \text{interp }\left\{a^{i_{3}}\right\} \to \left\{w^{i_{3}}\right\} \text{ at } a^{i_{3-}} \end{split}$$

Illustration

- 1. Numbering: Different levels of end-of-period assets, a^{i_a}
- 2. **Problem:** Find the consumption function at m_1 and m_2
- 3. Largest value-of-choice: Denoted by the triangles

Source: Druedahl and Jørgensen (2017), G^2EGM

Example

Beg.-of-period value function:

$$\underline{v}_{t+1}(a_t) = \sqrt{m_{t+1}} + \eta \max{\{m_{t+1} - \underline{m}, 0\}}$$
 where $m_{t+1} = (1+r)a_t + 1$

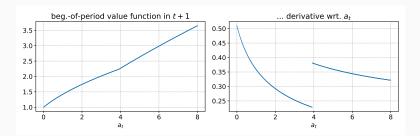

Derivative:

$$\underline{v}_{a,t+1}(a_t) = \frac{1}{2}(1+r)m_{t+1}^{-\frac{1}{2}} + (1+r)\eta \mathbf{1} \{m_{t+1} > \underline{m}\}$$

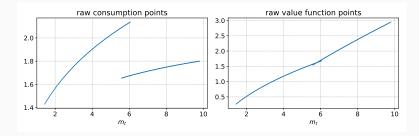

Budget constraint:

$$a_t + c_t = (1+r)a_{t-1} + 1$$

Next-period values

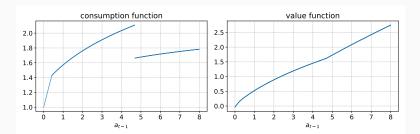

Raw values of c^{i_a} and v^{i_a}

Problem: Overlaps \Rightarrow not a function m_t !

Result after upper envelope

General problem structure

General problem structure with nesting:

$$\begin{split} \overline{v}_t\left(\overline{x}_t, d_t, e_t, m_t\right) &= \max_{c_t \in [0, m_t]} u(c_t, d_t, e_t) + \beta \underline{v}_{t+1} \left(\underline{\Gamma}_t \left(\overline{x}_t, d_t, e_t, a_t\right)\right) \\ & \text{with } a_t = m_t - c_t \\ v(x_t) &= \max_{d_t \in \Omega^d(x_t)} \overline{v}_t \left(\overline{\Gamma}_t \left(x_t, d_t\right)\right) \\ &\underline{v}_t \left(\underline{x}_t\right) = \max_{e_t \in \Omega^e(\underline{x}_t)} \mathbb{E}\left[v \left(\Gamma \left(\underline{x}_t, e_t\right)\right) \mid \underline{x}_t, e_t\right] \end{split}$$

- Finding c_t : EGM with upper envelope can (typically) still be used
- Finding d_t and e_t :
 - 1. Combination of discrete and continuous choices
 - 2. Typically requires use of numerical optimizer or root-finder
- Druedahl (2021), »A Guide on Solving Non-Convex Consumption-Saving Models« (costly with extra states in v̄)

Non-FIRE

Motivating example

- FIRE: Full International Rational Expectations
- **IKC**: $d\mathbf{Y} = \mathbf{M}^r d\mathbf{r} + \mathbf{M} d\mathbf{Y}$ where $M_{t,s} = \frac{\partial C_t}{\partial Y_s}$ and similar for \mathbf{M}^r
- Myopic behavior:
 - 1. Agents never thinks about the future
 - 2. Agents gradually observe current aggregate variables

$$m{M}^{
m myopic} = \left[egin{array}{cccc} M_{0,0} & 0 & 0 & \cdots \ M_{1,0} & M_{0,0} & 0 & \cdots \ M_{2,0} & M_{1,0} & M_{0,0} & \cdots \ dots & dots & dots & dots & dots \end{array}
ight]$$

Consider t = 1:

- M_{1,0}dY₀: Effect from past shock observed
- $M_{0,0}dY_1$: Effect of unexpected change in period 1

Sticky expectations

• Sticky expectations: A fraction $1-\theta$ updates expectations each period (from Carroll et. al., 2020)

$$m{M}^{
m sticky} = egin{bmatrix} M_{0,0} & (1- heta)M_{0,1} & (1- heta)M_{0,2} & \cdots \ M_{1,0} & (1- heta)M_{1,1} + heta M_{0,0} & (1- heta)M_{1,2} + heta (1- heta)M_{0,1} & \cdots \ M_{2,0} & (1- heta)M_{2,1} + heta M_{1,0} & dots & \ddots \ dots & dots & dots & dots & dots \ \end{pmatrix}$$

Consider t = 0:

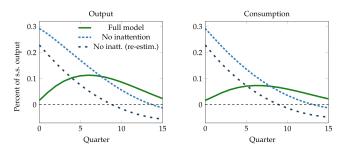

- 1. Non-updaters: $\theta M_{0,0} dY_0$
- 2. Updaters: $(1-\theta)\sum_{s>0} M_{0,s} dY_s$

Consider t = 1:

- 1. Ingoing updaters: $(1-\theta)\sum_{s>0} M_{1,s} dY_s$
- 2. Ingoing non-updaters: $\theta \left(M_{1,0} dY_0 + M_{0,0} dY_1 \right)$
- 3. New updaters: $\theta(1-\theta)\sum_{s>1} M_{0,s} dY_{s+1}$

Hump-shaped response to monetary policy

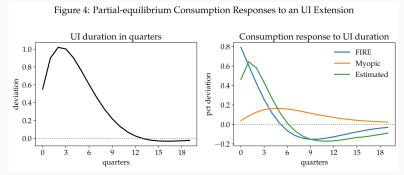

Figure 4: Impulse responses with and without inattention

Note. This figure shows the general equilibrium paths of output and consumption in our estimated HA model with different assumptions on inattention. The solid green uses our baseline estimates of household inattention. The dashed blue line is the impulse response when the inattention parameter is set to $\theta=0$, holding all other parameters fixed at their estimated value in table 2. The dotted dark blue line reestimates the model parameters without inattention.

UI extensions might be less powerful

Source: Bardóczy and Guerreiro (2020), »Unemployment Insurance in Macroeconomic Stabilization with Imperfect Expectations«

HANK-SAM

My ongoing work

Zero liqduity:

Broer, Druedahl, Harmenberg and Öberg (2023), »The Unemployment-Risk Channel in Business-Cycle Fluctuations«

Positive liqudity:

Broer, Druedahl, Harmenberg and Öberg (2023), »Fiscal stimulus policies according to HANK-SAM«

Code: HANK-SAM in GEModelToolsNotebooks

Household problem

$$\begin{aligned} v_t(\beta_i, u_{it}, a_{it-1}) &= \max_{c_{it}, a_{it}} \frac{c_{it}^{1-\sigma}}{1-\sigma} + \beta_i \mathbb{E}_t \left[v_{t+1} \left(\beta_i, u_{it+1}, a_{it} \right) \right] \\ \text{s.t. } a_{it} + c_{it} &= (1+r_t)a_{it-1} + (1-\tau_t)y_t(u_{it}) + \mathsf{div}_t + \mathsf{transfer}_t \\ a_{it} &\geq 0 \end{aligned}$$

- 1. Dividends and government transfers: div_t and transfer_t
- 2. Real wage: w_t
- 3. Income tax: τ_t
- 4. **Separation rate** for employed: δ_t
- 5. **Job-finding rate** for unemployed: $\lambda_t^{u,s} s(u_{it-1})$ (where $s(u_{it-1})$ is exogenous search effectiveness)
- 6. US-style duration-dependent **UI system:**
 - a) High replacement rate $\overline{\phi}$, first \overline{u} months
 - b) Low replacement rate ϕ , after \overline{u} months

Income process

Income is

$$y_{it}(u_{it}) = w_{ss} \cdot egin{cases} 1 & ext{if } u_{it} = 0 \ \overline{\phi} \mathsf{UI}_{it} + (1 - \mathsf{UI}_{it}) \underline{\phi} & ext{else} \end{cases}$$

where share of the month with UI is

$$\mathsf{UI}_{it} = egin{cases} 0 & \text{if } u_{it} = 0 \ 1 & ext{else if } u_{it} < \overline{u}_t \ 0 & ext{else if } u_{it} > \overline{u}_t + 1 \ \overline{u} - \left(u_{it} - 1
ight) & ext{else} \end{cases}$$

• Note: Hereby \overline{u} becomes a continuous variables

Transition probabilities

Beginning-of-period value function:

$$\underline{v}_{t}\left(\beta_{i}, u_{it-1}, a_{it-1}\right) = \mathbb{E}\left[v_{t}(\beta_{i}, u_{it}, a_{it-1}) \mid u_{it-1}, a_{it-1}\right]$$

- Grids: $u_{it} \in \{0, 1, \dots, \#_u 1\}$ for $\#_u 1$
- Workers with $u_{it-1} = 0$:

$$u_{it} = egin{cases} 0 & \text{with } 1 - \delta_t \\ 1 & \text{with } \delta_t \end{cases}, \ \mathsf{UI}_{it} = egin{cases} 1 & \text{with } \pi^{\mathsf{UI}} \\ 0 & \text{with } 1 - \pi^{\mathsf{UI}} \end{cases}$$

• **Unemployed** with $u_{it-1} = 1$:

$$u_{it} = \begin{cases} 0 & \text{with } \lambda_t^{u,s} s(u_{it-1}) \\ \min \{u_{it-1} + 1, \#_u - 1\} & \text{with } 1 - \lambda_t^{u,s} s(u_{it-1}) \end{cases}, \, \mathsf{UI}_{it} = \mathsf{UI}_{it-1}$$

Hiring and firing

Job value:

$$V_t^j = p_t^{\scriptscriptstyle{\mathsf{X}}} Z_t - w_{\!s\!s} + eta^{\mathsf{firm}} \mathbb{E}_t \left[(1 - \delta_{\!s\!s}) V_{t+1}^j
ight]$$

Vacancy value:

$$V_t^{
m v} = -\kappa + \lambda_t^{
m v} V_t^j + (1-\lambda_t^{
m v})(1-\delta_{
m ss})eta^{
m firm} \mathbb{E}_t \left[V_{t+1}^{
m v}
ight]$$

• Free entry implies

$$V_t^v = 0$$

Labor market dynamics

Labor market tightness is given by

$$\theta_t = \frac{v_t}{S_t}$$

Cobb-Douglas matching function implies:

$$\lambda_t^v = A\theta_t^{-\alpha}$$
$$\lambda_t^{u,s} = A\theta_t^{1-\alpha}$$

Law of motion for unemployment:

$$u_t = u_{t-1} + \delta_t (1 - u_{t-1}) - \lambda_t^{u,s} S_t$$

Standard New Keynesian block

- Intermediate goods price: p_t^X
- Dixit-Stiglitz demand curve ⇒ Phillips curve relating marginal cost, MC_t = p_t^x, and final goods price inflation, Π_t = P_t/P_{t-1},

$$1 - \epsilon + \epsilon p_t^{\mathsf{x}} = \phi \pi_t (1 + \pi_t) - \phi \beta^{\mathsf{firm}} \mathbb{E}_t \left[\pi_{t+1} (1 + \pi_{t+1}) \frac{Y_{t+1}}{Y_t} \right]$$

with output $Y_t = Z_t(1 - u_t)$

- Flexible price limit: $\phi \to 0$
- Taylor rule:

$$1+i_t = (1+i_{ss})\left(rac{1+\pi_t}{1+\pi_{ss}}
ight)^{\delta_{\pi}}$$

Government

- Total expenses: $X_t = \Phi_t + G_t + \text{transfer}_t$
- Total taxes: $taxes_t = \tau_t (\Phi_t + w_{ss}(1 u_t))$
- Government budget is

$$q_t B_t = (1 + q_t \delta_q) B_{t-1} + X_t - \mathsf{taxes}_t$$

Tax rule:

$$egin{aligned} ilde{ au}_t &= rac{\left(1 + q_t \delta_q
ight) B_{t-1} + X_t - q_{ss} B_{ss}}{\Phi_t + w_{ss} (1 - u_t)} \ au_t &= \omega ilde{ au}_t + (1 - \omega) au_{ss} \end{aligned}$$

Equilibrium

1. Financial markets:

$$\begin{split} \frac{1+\delta_q q_{t+1}}{q_t} &= \frac{1+i_t}{1+\pi_{t+1}} \\ 1+r_t &= \begin{cases} \frac{(1+\delta_q q_0)B_{-1}}{A^{hh}_{-1}} & \text{if } t=0 \\ \frac{1+i_{t-1}}{1+\pi_t} & \text{else} \end{cases} \end{split}$$

2. Market clearing:

$$A_t^{hh} = q_t B_t$$
$$Y_t = C_t^{hh} + G_t$$

Summary

Summary

Mixed advanced:

- 1. Policies (shocks, targets, rule, optimal)
- 2. Life-cycle (age, mortality, income profile)
- Endogenous idiosyncratic risk (external/internal)
- 4. Discrete choices with taste shocks (upper envelope, non-convex)
- 5. Bounded rationality (manipulation of Jacobian, myopic, sticky)
- HANK-SAM (labor market dynamics, fiscal policy)
